Search for top-quark partners with charge 5/3 in the same-sign dilepton final state

The CMS Collaboration^{*}

Abstract

A search for the production of heavy partners of the top quark with charge 5/3 is performed in events with a pair of same-sign leptons. The data sample corresponds to an integrated luminosity of 19.5 fb^{-1} and was collected at $\sqrt{s} = 8 \text{ TeV}$ by the CMS experiment. No significant excess is observed in the data above the expected background and the existence of top-quark partners with masses below 800 GeV is excluded at a 95% confidence level, assuming they decay exclusively to tW. This is the first limit on these particles from the LHC, and it is significantly more restrictive than previous limits.

Submitted to Physical Review Letters

Various extensions of the standard model (SM) address the hierarchy problem by predicting the existence of heavy partners for the top quark [1–4]. These “top-quark partners” are expected to have masses close to the electroweak symmetry breaking scale and thus would be accessible at the Large Hadron Collider (LHC). They may also have exotic charge and would not contribute to the coupling of the Higgs boson to gluons [5]. For this reason, their existence is not excluded by the recent observation of a Higgs boson with a mass of 125 GeV and properties consistent with those of a SM Higgs particle [6–8] and searches for top-quark partners continue to be important for testing the validity of several new physics scenarios [1–4]. Theoretical predictions suggest that searches in the mass region from 500 GeV to 1.5 TeV present the greatest potential for discovery at the LHC [2, 9].

This Letter presents a search for exotic top-quark partners using LHC pp collision data collected by the Compact Muon Solenoid (CMS) experiment at a center-of-mass energy $\sqrt{s} = 8$ TeV. The analysis is based on a data sample corresponding to an integrated luminosity of 19.5 fb^{-1} . We look for the $T_{5/3}$, an exotic top-quark partner with charge $5e/3$ (where $-e$ is the charge of the electron). We assume that the $T_{5/3}$ is pair-produced via either gluon fusion or quark annihilation and decays via $T_{5/3} \rightarrow tW^+$ followed by $t \rightarrow W^+b$ (charge conjugate modes are implied throughout this Letter). Single $T_{5/3}$ production is not considered because it is more model dependent and presents a different event topology [2].

We focus on the dilepton final state wherein, for one or both of the $T_{5/3}$, its two W bosons both decay into leptons, which will have the same sign. Due to the presence of the two bottom quarks and the possibility of hadronic decays for one of the top-quark partners, this final state also includes significant jet activity. The leptons considered in this analysis are electrons and muons. The presence of same-sign leptons distinguishes this process from $t\bar{t}$, making the contribution of the latter comparable to backgrounds with much smaller cross sections: $t\bar{t}W$, $t\bar{t}WW$, $t\bar{t}Z$, WWW , and same-sign WW . Because of its large cross section, $t\bar{t}$ still contributes to the overall background through instrumental effects such as charge misidentification in dilepton decays, as well as through $t\bar{t}$ events where the W boson from one top quark decays leptonically and the second lepton arises from a b -quark decay. Additional processes that contribute to the expected background include QCD multijets, $W/Z+jets$, and dibosons (WZ and ZZ). A previous search using a signature of same-sign leptons, multiple jets, and missing transverse energy was performed by the CDF experiment and excludes $T_{5/3}$ masses below 365 GeV at the 95% confidence level (CL) [10].

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the superconducting solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter. Muons are measured in gas-ionization detectors embedded in the steel flux return yoke outside the solenoid. In addition, the CMS detector has extensive forward calorimetry. The first level of the CMS trigger system, composed of custom hardware processors, uses information from the calorimeters and muon detectors to select the most interesting events, with a latency of less than $4 \mu\text{s}$. The High Level Trigger processor farm further decreases the event rate from around 100 kHz to around 0.5 kHz, before data storage. A more detailed description of the CMS detector can be found elsewhere [11].

The pair produced top-quark partner signal events were simulated using the MADGRAPH 5.1.1 [12] event generator, and twelve samples corresponding to values of the $T_{5/3}$ mass from 350 GeV to 1 TeV were produced. The PYTHIA 6.426 [13] generator was used for parton showering, hadronization, and simulation of the underlying event. The CTEQ6L [14] parton distribution functions were used and the PYTHIA parameters for the underlying event were set to the Z2* [15] tune.

The detector response was modeled using GEANT4 [16]. The next-to-next-to-leading-order cross section for $T_{5/3}$ pair production was found to vary from 5.3 pb at the mass of 350 GeV to 3.4 fb at the mass of 1 TeV [17]. The uncertainty on the cross section in the mass range used for the analysis is about 5%.

The background processes include $t\bar{t}$, $W(\rightarrow \ell\nu) + \text{jets}$, $Z/\gamma^*(\rightarrow \ell\ell) + \text{jets}$, and dibosons (WZ and ZZ). Additional low-rate SM processes were also considered: $W^\pm W^\pm$, WWW , $t\bar{t}W$, $t\bar{t}WW$, and $t\bar{t}Z$. These were all simulated by means of MADGRAPH with PYTHIA used for hadronization. Next-to-leading-order or, where available, next-to-next-to-leading order cross sections were employed.

For all the simulated samples, the additional proton-proton interactions in each beam crossing (pileup) were modeled by superimposing minimum bias interactions onto simulated events, weighted such that the number of interactions agreed with the distribution observed in data.

This analysis relies on the reconstruction of three object types: electrons, muons, and jets. The events are reconstructed using the CMS “particle-flow” (PF) event description algorithm [18, 19]. Candidate events are required to have at least two leptons with the same charge that are within the detector acceptance ($|\eta| < 2.4$) and to have passed triggers based on dielectrons, dimuons, or electron-muon combinations. Here, η is the pseudorapidity defined as $\eta \equiv -\ln[\tan(\theta/2)]$, where θ is the polar angle with respect to the counterclockwise beam direction. Candidate events must also have at least one good reconstructed primary vertex matched to the tracks of the two selected leptons. Candidate electrons are reconstructed using energy deposits in the ECAL and a track from the silicon detectors. The shape of the electron shower in the ECAL must be consistent with that of an electromagnetic object and the shower must be well matched to the extrapolated track. Additional requirements are imposed to reject electrons produced by photon conversions. The charge of the electron candidates is measured using three different methods. Two of the measurements are based on two different tracking algorithms: the standard CMS track reconstruction algorithm [20] and the Gaussian Sum Filter algorithm [21], optimized to take into account the possible emission of bremsstrahlung photons in the silicon tracker. The third measurement is based on the relative position of the calorimeter cluster and the projected track from the pixel detector. All three measurements are required to agree. For selection, muons are required to be reconstructed by both the silicon tracker and the muon system and the combined fit of the track must be of good quality (χ^2 per degree of freedom less than ten).

All selected leptons are required to be isolated. The isolation for each lepton is estimated by first computing the scalar sum of the transverse momenta of all neutral and charged reconstructed particle candidates, except the lepton itself, within a cone of size $\Delta R \equiv \sqrt{(\Delta\phi)^2 + (\Delta\eta)^2}$ around the lepton, where ϕ is the azimuthal angle. This sum is then divided by the transverse momentum (p_T) of the lepton to calculate the relative isolation (I_R). The values for the cone size and the maximum allowed I_R are $\Delta R = 0.3$ (0.4) and $I_R = 0.15$ (0.20) respectively for electrons (muons). An event-by-event correction is applied to the computation of the lepton isolation in order to account for the effect of pileup. Data-to-simulation efficiency scale factors are obtained using the tag-and-probe method [22] for lepton identification and isolation as a function of lepton p_T and η , and are applied as corrections to the number of simulated events passing the selection. In addition, we define a category of “loose” leptons with some of the isolation and identification requirements relaxed. The I_R threshold for these leptons is increased from 0.15 to 0.60 for electrons and from 0.20 to 0.40 for muons.

For the range of $T_{5/3}$ masses accessible at $\sqrt{s} = 8$ TeV, the analysis exploits advanced techniques in jet reconstruction for identifying boosted top quarks and W bosons that decay hadron-

ically. In particular, if the top quarks are highly boosted ($p_T > 400 \text{ GeV}$), their decay products are collimated and merged into one jet. We use a “top-quark tagging” algorithm based on identifying jet substructure [23] to reconstruct such merged top-quark jets. Jets are clustered using the Cambridge–Aachen algorithm [24, 25], as implemented in FASTJET version 3 [26], with a distance parameter of $R = 0.8$ in η - ϕ space (CA8 jets). The CA8 top-quark jets are required to have $p_T > 400 \text{ GeV}$ and more than two subjets found by the top-quark tagging algorithm. The jet mass must be consistent with the mass of the top quark and the minimum pairwise mass of the three highest p_T subjets is required to be greater than 50 GeV .

The decay products of W bosons from the $T_{5/3}$ decay or from a boosted top quark, for which the b quark is reconstructed independently, may also merge into a single jet. We use a “jet pruning” algorithm [27] to identify the hadronic decay of such W bosons. This algorithm also uses CA8 jets as inputs with the parameters taken from the original theoretical papers [28, 29]. CA8 W-boson jets are required to have $p_T > 200 \text{ GeV}$, exactly two subjets, and their mass must be consistent with that of the W boson [30].

To account for W bosons and top quarks that are not boosted, jets are also reconstructed using the anti- k_T algorithm [31] with a distance parameter of 0.5 (AK5). These jets are required to have $p_T > 30 \text{ GeV}$. If an AK5 jet overlaps with a top-quark jet or a W-boson jet ($\Delta R < 0.8$), the AK5 jet is discarded. For the simulated samples, additional smearing is applied to the AK5 jet p_T ($\sim 7\text{--}19\%$ depending on η) to correct for the better jet energy resolution seen in the simulation compared to data.

All of the above categories of jets are required to have $|\eta| < 2.4$ and PF jet identification [32]. Jet energy corrections are applied to account for residual non-uniformity and non-linearity of the detector response. Jet energies are also corrected by subtracting the average contribution of particles from pileup [33, 34]. All jets must be $\Delta R \geq 0.3$ away from the selected leptons and, as mentioned above, $\Delta R \geq 0.8$ away from any other jet. A correction to account for differences in the identification efficiency of W-boson and top-quark jets between data and simulation is applied [35].

The signal selection, optimized to yield the best signal sensitivity, requires:

- At least two isolated same-sign leptons as defined above with $p_T > 30 \text{ GeV}$. Neither of these leptons may be inside a top-quark jet, so we require $\Delta R > 0.8$.
- Dilepton Z boson veto: $M(\text{ee}) < 76 \text{ GeV}$ or $M(\text{ee}) > 106 \text{ GeV}$. This selection applies only to the dielectron channel. If the muon charge is mismeasured, its momentum will also be mismeasured so a selected muon pair from a Z boson will not fall within this invariant mass range.
- Trilepton Z boson veto: $M(\ell\ell) < 76 \text{ GeV}$ or $M(\ell\ell) > 106 \text{ GeV}$ where $M(\ell\ell)$ is the invariant mass of either one of the selected leptons and any other same flavor opposite-sign lepton in the event with $p_T > 15 \text{ GeV}$ that satisfies the loose lepton criteria.
- $N_c \geq 7$, where N_c is the number of constituents identified in the event. For the purpose of this selection, each AK5 jet and each lepton with the same properties as the two same-sign leptons counts as one constituent. Since a W-boson jet is assumed to correspond to a W boson, each such jet counts as two constituents. Likewise, each top-quark jet represents a top quark and counts as three constituents.
- $H_T > 900 \text{ GeV}$, where H_T is the scalar sum of the p_T of all selected jets and leptons in the event.

With these criteria, the signal efficiency is 10–13% for $T_{5/3}$ masses between 750 and 1000 GeV.

The backgrounds associated with this analysis fall into three main categories. First, they may originate from SM processes leading to prompt, same-sign dilepton signatures, including diboson production (WZ and ZZ), $t\bar{t}W$, $t\bar{t}WW$, $t\bar{t}Z$, $W^\pm W^\pm$, and WWW . The contribution of these backgrounds is obtained from simulation.

The second category consists of events from processes with prompt, opposite-sign leptons, such as $t\bar{t}$ and Drell–Yan production, in which one of the leptons is misreconstructed with the wrong charge, leading to a same-sign dilepton final state. For muons in the p_T range considered in this analysis, the charge misidentification rate is extremely small (of order 10^{-4}) and its contribution to the background is negligible [36]. For electrons, the charge misidentification probability ($\sim 10^{-3}$) is derived from the data using a sample dominated by Drell–Yan events obtained by inverting the dilepton Z boson veto and using the ratio of same-sign Z boson candidates to the total number of candidates. The number of expected same-sign events due to charge misidentification is then estimated by considering the total number of events passing the full selection, but having oppositely charged leptons. These events are weighted by the charge misidentification probability parametrized as a function of the electron p_T and η to obtain the contribution of this background type.

The third category consists of events with one or more “non-prompt leptons”. This is the primary instrumental background arising from jets being misidentified as leptons, non-prompt leptons passing tight isolation selection criteria, and other such phenomena. This contribution is estimated using the “Tight-Loose” method described in [37]. “Tight” leptons have the same definition as those used in the analysis, whereas “loose” leptons are defined earlier. The background is estimated by using events with one or more loose leptons weighted by the ratios of the numbers of tight leptons to the numbers of loose leptons expected for prompt and non-prompt leptons. The ratio for prompt leptons is determined from Drell–Yan events where the invariant mass of the leptons is within 10 GeV of the Z boson mass. The non-prompt ratio is determined from a sample enriched in background by requiring exactly one lepton, low missing transverse energy ($E_T^{\text{miss}} < 25 \text{ GeV}$), low transverse mass ($M_T < 25 \text{ GeV}$), and at least one jet with $p_T > 40 \text{ GeV}$ and $\Delta R > 1.0$ with respect to the lepton.

The systematic uncertainties that affect this analysis include uncertainties in the efficiency of the trigger (1%), lepton reconstruction and identification efficiency (1% per lepton), pileup, and jet energy scale (JES). The uncertainties due to JES and pileup are obtained by varying the respective quantities in simulation. For the signal, the JES and pileup uncertainties correspond to 2% and 3%, respectively. For the simulated backgrounds, they range from 3 to 6% depending on the sample. In addition, we assign a constant 3% uncertainty due to the JES of CA8 jets for all simulated samples [35]. The dominant uncertainty in the expected event yields due to backgrounds derived from simulation is the overall normalization uncertainty. The WZ (17%), ZZ (5.1%), and $t\bar{t}W$ (32%) normalization uncertainties are taken from Refs. [38], [39], and [40], respectively. For the other rare backgrounds, we assume a conservative normalization uncertainty of 50%. An uncertainty of 20% is assigned to the background contribution from charge misidentification, based on the variation of the charge misidentification rate between Drell–Yan data and $t\bar{t}$ simulation. We assign an additional uncertainty to the background contribution estimated with the “Tight-Loose” method, due to the non-prompt ratio measured in the background-enriched sample not matching that of the events after the full selection. Following Ref. [36], we assess this uncertainty to be 50%. We also include a 2.6% uncertainty due to the luminosity [41] for all event yields that are derived from simulation.

The final numbers of observed and expected events are reported in Table 1 for each of the three lepton channels (ee , $e\mu$, and $\mu\mu$) and their combination. Figure 1 shows the H_T distribution for

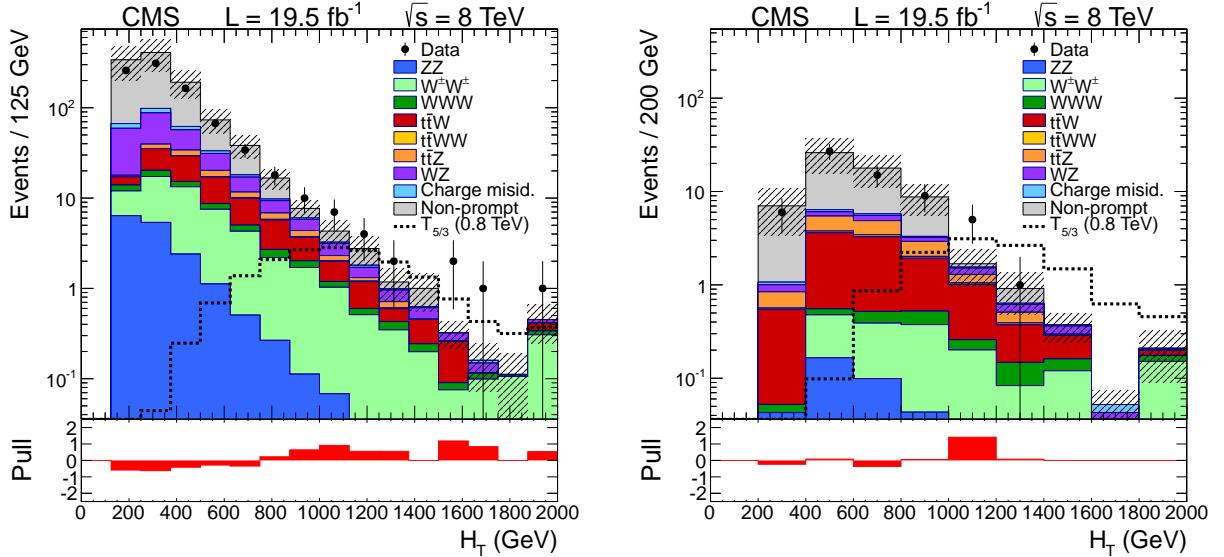

Figure 1: The distribution of H_T for all channels combined after the same-sign selection, the lepton invariant mass vetoes, and a requirement of at least four constituents (left) and after the full selection except for the H_T requirement itself (right). The shaded band represents the total uncertainty in the predicted backgrounds. The final bin includes all overflow events.

all channels combined, at two different steps of the selection process.

Table 1: Summary table of expected and observed numbers of events for all channels. The expected yield is composed of the same-sign backgrounds, the contribution due to charge misidentification, and that due to misreconstructed leptons. All systematic uncertainties are included. Also shown is the expected contribution from a $T_{5/3}$ with mass 800 GeV.

Channel	ee	e μ	$\mu\mu$	All
Same-sign	0.8 ± 0.2	1.9 ± 0.4	1.3 ± 0.3	4.0 ± 0.8
Chrg. misid.	0.06 ± 0.02	0.04 ± 0.01	—	0.11 ± 0.02
Non-prompt	1.9 ± 1.2	0.6 ± 0.9	0.3 ± 0.6	2.8 ± 1.9
Tot. bkgnd	2.7 ± 1.3	2.5 ± 1.0	1.6 ± 0.7	6.8 ± 2.1
Obs. events	0	6	3	9
$T_{5/3}$	2.1 ± 0.1	4.7 ± 0.3	2.8 ± 0.2	9.7 ± 0.5

No significant excess is observed. Exclusion limits are computed at 95% CL by using the ROOSTATS implementation [42] of the Bayesian approach. We use a cut-and-count method and compare the numbers of observed events with the numbers of expected signal and background events. A flat prior is used for the signal production cross section. The event yields from all lepton channels are combined when setting the limits. Upper bounds are set on the production cross section of heavy top-quark partners assuming a 100% branching fraction for the decay $T_{5/3} \rightarrow tW$. The resulting expected and observed limits are shown in Fig. 2. The expected lower limit on the mass of the $T_{5/3}$ is 830 GeV and the observed limit is 800 GeV.

The use of recently developed jet substructure techniques in this analysis for identifying boosted top quarks and W bosons enables us to probe cross sections of $T_{5/3}$ pair production that are between 10–20% lower than would otherwise be possible for $T_{5/3}$ masses in the range 800–1000 GeV. The reconstruction of the $T_{5/3}$ mass benefits as well and this can, in the event of a discovery in the future, be used to distinguish a $T_{5/3}$ from other exotic particles which decay in a similar manner.

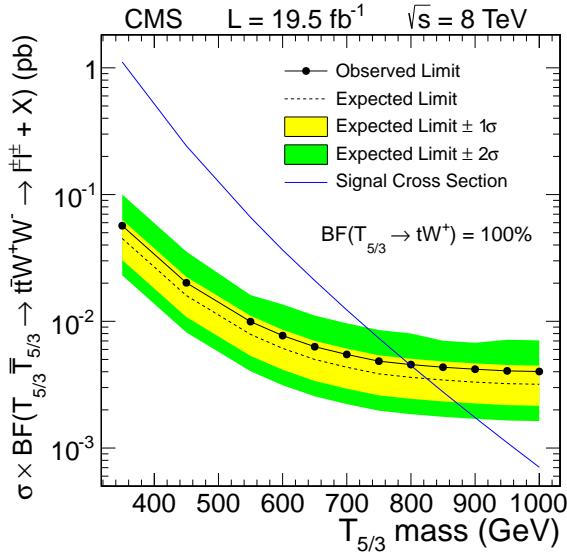

Figure 2: Expected and observed 95% CL limits on the $T_{5/3}$ production cross section times the branching fraction for decay to same-sign dileptons. The 1σ and 2σ combined statistical and systematic expected variations are shown as yellow (light) and green (dark) bands, respectively.

In summary, a search for an exotic top partner with charge 5/3 in same-sign dileptonic events has been performed using 19.5 fb^{-1} of data collected by the CMS experiment at $\sqrt{s} = 8 \text{ TeV}$. No significant excess is observed in the data above the expected standard model background. An upper bound at the 95% confidence level is set on the production cross section of heavy top-quark partners assuming a 100% branching fraction for the decay $T_{5/3} \rightarrow tW$, and masses below 800 GeV are excluded. This is the first limit on $T_{5/3}$ production from the LHC and it is significantly more restrictive than the 365 GeV limit set by previous searches.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NKTH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); NRF and WCU (Republic of Korea); LAS (Lithuania); CINVESTAV, CONACYT, SEP, and UASLP-FAI (Mexico); MSI (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS and RFBR (Russia); MESTD (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); NSC (Taipei); ThEPCenter, IPST, STAR and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Rekovic, J. Robles, S. Salur, S. Schnetzer, C. Seitz, S. Somalwar, R. Stone, S. Thomas, P. Thomassen, M. Walker

University of Tennessee, Knoxville, USA

K. Rose, S. Spanier, Z.C. Yang, A. York

Texas A&M University, College Station, USA

O. Bouhali⁶¹, R. Eusebi, W. Flanagan, J. Gilmore, T. Kamon⁶², V. Khotilovich, V. Krutelyov, R. Montalvo, I. Osipenkov, Y. Pakhotin, A. Perloff, J. Roe, A. Safonov, T. Sakuma, I. Suarez, A. Tatarinov, D. Toback

Texas Tech University, Lubbock, USA

N. Akchurin, C. Cowden, J. Damgov, C. Dragoiu, P.R. Dudero, K. Kovitanggoon, S. Kunori, S.W. Lee, T. Libeiro, I. Volobouev

Vanderbilt University, Nashville, USA

E. Appelt, A.G. Delannoy, S. Greene, A. Gurrola, W. Johns, C. Maguire, Y. Mao, A. Melo, M. Sharma, P. Sheldon, B. Snook, S. Tuo, J. Velkovska

University of Virginia, Charlottesville, USA

M.W. Arenton, S. Boutle, B. Cox, B. Francis, J. Goodell, R. Hirosky, A. Ledovskoy, C. Lin, C. Neu, J. Wood

Wayne State University, Detroit, USA

S. Gollapinni, R. Harr, P.E. Karchin, C. Kottachchi Kankamamge Don, P. Lamichhane, A. Sakharov

University of Wisconsin, Madison, USA

D.A. Belknap, L. Borrello, D. Carlsmith, M. Cepeda, S. Dasu, S. Duric, E. Friis, M. Grothe, R. Hall-Wilton, M. Herndon, A. Hervé, P. Klabbers, J. Klukas, A. Lanaro, R. Loveless, A. Mohapatra, I. Ojalvo, T. Perry, G.A. Pierro, G. Polese, I. Ross, T. Sarangi, A. Savin, W.H. Smith

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 3: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
- 4: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia
- 5: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
- 6: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 7: Also at California Institute of Technology, Pasadena, USA
- 8: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
- 9: Also at Zewail City of Science and Technology, Zewail, Egypt
- 10: Also at Suez Canal University, Suez, Egypt
- 11: Also at Cairo University, Cairo, Egypt
- 12: Also at Fayoum University, El-Fayoum, Egypt
- 13: Also at British University in Egypt, Cairo, Egypt
- 14: Now at Ain Shams University, Cairo, Egypt
- 15: Also at Université de Haute Alsace, Mulhouse, France
- 16: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 17: Also at Brandenburg University of Technology, Cottbus, Germany
- 18: Also at The University of Kansas, Lawrence, USA
- 19: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 20: Also at Eötvös Loránd University, Budapest, Hungary
- 21: Also at Tata Institute of Fundamental Research - EHEP, Mumbai, India
- 22: Also at Tata Institute of Fundamental Research - HEGR, Mumbai, India
- 23: Now at King Abdulaziz University, Jeddah, Saudi Arabia
- 24: Also at University of Visva-Bharati, Santiniketan, India
- 25: Also at University of Ruhuna, Matara, Sri Lanka
- 26: Also at Isfahan University of Technology, Isfahan, Iran
- 27: Also at Sharif University of Technology, Tehran, Iran
- 28: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 29: Also at Università degli Studi di Siena, Siena, Italy
- 30: Also at Centre National de la Recherche Scientifique (CNRS) - IN2P3, Paris, France
- 31: Also at Purdue University, West Lafayette, USA
- 32: Also at Universidad Michoacana de San Nicolas de Hidalgo, Morelia, Mexico
- 33: Also at National Centre for Nuclear Research, Swierk, Poland
- 34: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia

-
- 35: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
 - 36: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
 - 37: Also at University of Athens, Athens, Greece
 - 38: Also at Paul Scherrer Institut, Villigen, Switzerland
 - 39: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
 - 40: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
 - 41: Also at Gaziosmanpasa University, Tokat, Turkey
 - 42: Also at Adiyaman University, Adiyaman, Turkey
 - 43: Also at Cag University, Mersin, Turkey
 - 44: Also at Mersin University, Mersin, Turkey
 - 45: Also at Izmir Institute of Technology, Izmir, Turkey
 - 46: Also at Ozyegin University, Istanbul, Turkey
 - 47: Also at Kafkas University, Kars, Turkey
 - 48: Also at Suleyman Demirel University, Isparta, Turkey
 - 49: Also at Ege University, Izmir, Turkey
 - 50: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
 - 51: Also at Kahramanmaraş Sütcü Imam University, Kahramanmaraş, Turkey
 - 52: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
 - 53: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
 - 54: Also at INFN Sezione di Perugia; Università di Perugia, Perugia, Italy
 - 55: Also at Utah Valley University, Orem, USA
 - 56: Also at Institute for Nuclear Research, Moscow, Russia
 - 57: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
 - 58: Also at Argonne National Laboratory, Argonne, USA
 - 59: Also at Erzincan University, Erzincan, Turkey
 - 60: Also at Yildiz Technical University, Istanbul, Turkey
 - 61: Also at Texas A&M University at Qatar, Doha, Qatar
 - 62: Also at Kyungpook National University, Daegu, Korea
